# Discrimination and Access to Capital: A Field Experiment in Ethiopia<sup>\*</sup>

Shibiru Ayalew Shanthi Manian Ketki Sheth

November 15, 2024

Access to capital is a major constraint for female business owners. In a large-scale field experiment in Ethiopia, we show that gender discrimination by loan officers is unlikely to contribute to gender gaps in capital access. We study whether loan officers discriminated against female owners in high-stakes capital allocation decisions affecting real businesses in a national business plan competition. In a sample of 3,696 evaluations, randomized business-owner gender did not affect capital decisions, either for the competition prizes or for consideration for a loan. Our confidence intervals are tight enough to exclude any meaningful gender discrimination in these decisions. An incentivized belief elicitation revealed that business-owner gender similarly did not affect beliefs about future business performance, implying that loan officers do not engage in statistical discrimination or taste-based discrimination. We confirm that loan officers' beliefs were accurate using machine learning to predict business outcomes after 18 months. Gender does not meaningfully improve targeting of high-performing businesses, suggesting no trade-off between gender equity and effective capital allocation.

This study was funded by the Center for Effective Global Action and International Growth Center, and implemented in collaboration with the Entrepreneurship Development Institute in Ethiopia. The study was approved by IRBs at the University of California, Merced, and Washington State University and pre-registered on the AEA registry (AEARCTR-0006518). We are grateful to Prashant Bharadwaj, Aislinn Bohren, Laura Gee, Leah Lakdawala, Ted Miguel, and participants at numerous seminars and conferences for helpful feedback.

## 1 Introduction

Capital is a key accelerator for business growth and productivity, yet female business owners in many low-income countries have less access to formal credit and earn lower profits.<sup>1</sup> Observable differences between male and female entrepreneurs explain only a small portion of the profit gap, suggesting that gender discrimination may be an important, yet understudied, factor inhibiting the success of female entrepreneurship (World Bank, 2019*b*). Financial providers, such as loan officers, may discriminate against female business owners either due to prejudice or because they use gender as a proxy for business performance. Both factors are commonly believed to be more pronounced in contexts with large gender disparities, such as Ethiopia. On the other hand, financial providers are experts in their field, face real stakes in how their portfolio performs, and have access to a significant amount of information about businesses they are evaluating, all of which reduce the likelihood of discrimination.

In addition to equity considerations, the response to gender in capital allocation decisions may have implications for profit maximization. If loan officers aim to identify and target capital to high-performing businesses, and gender does, in fact, predict business performance, then gender discrimination may be an effective profit-maximizing strategy.<sup>2</sup> Indeed, standard theories of discrimination suggest that discrimination should only persist when it is profitmaximizing.<sup>3</sup> However, empirical studies have documented discrimination from prejudice and inaccurate beliefs, even when it reduces profits (Guryan and Charles, 2013).

These equity and profit-maximization implications depend not only on whether loan offi-

<sup>&</sup>lt;sup>1</sup>See, for example, Blattman, Fiala and Martinez (2014); World Bank (2019*a*); Hardy and Kagy (2020). In Ethiopia, male managers are more likely to take out loans and tend to borrow significantly more than female managers (World Bank, 2019*a*). Similarly, the 2015 World Enterprise Surveys found that among firms with five or more employees, 49.1 percent of female-led firms identified access to finance as a major constraint, compared to 18.8 percent of male-led firms, and that 44.9 percent of female-led firms were fully credit-constrained versus 35.7 percent of male-led firms (World Bank, 2024).

<sup>&</sup>lt;sup>2</sup>High-performing (i.e., profitable) businesses increase the likelihood of repayment and the returns to capital. We conducted numerous interviews with loan officers confirming that the profitability of a business is a key factor in loan decisions.

<sup>&</sup>lt;sup>3</sup>The Becker model (i.e., taste-based discrimination) implies that discriminatory financial providers will only remain in the market if discrimination is profit-maximizing (Becker, 1957). The theory of statistical discrimination demonstrates that it can indeed be profit-maximizing if discrimination is based on accurate beliefs on gender and business performance (Phelps, 1972; Arrow, 1974; Aigner and Cain, 1977; Bohren, Imas and Rosenberg, 2019).

cers discriminate, but also on the source of discrimination. Researchers generally distinguish between two possible sources of discrimination: preferences (i.e., taste-based discrimination (Becker, 1957)) or differing beliefs about female-owned versus male-owned businesses (i.e., belief-based or statistical discrimination (Phelps, 1972; Arrow, 1974; Aigner and Cain, 1977)). Each source of discrimination, as well as the accuracy of the beliefs held by loan officers, has different welfare impacts and policy implications (Bohren et al., 2023). Our study addresses each of these questions in turn: whether loan officers discriminate in making capital allocation decisions, the extent of each source of discrimination, and whether the beliefs held by loan officers are accurate. By exploring these key questions, we go beyond measuring discrimination to evaluate the implications of our results for profit maximization (i.e., targeting high-performing businesses).

We study these questions by embedding a field experiment in the natural context of a large business plan competition in Ethiopia. We identify discrimination by randomly assigning business-owner gender in the evaluation of the competition. Business owners throughout Ethiopia completed an application form designed to mimic information commonly captured in an initial application for a loan.<sup>4</sup> We recruited 84 loan officers from thirteen different financial institutions to evaluate 916 real businesses that applied to the competition. For each business, the loan officers provided a score used to determine the competition grants and prizes, decided whether to forward the application to their own lending institution to be considered for a loan, and predicted how the business would perform in the future (both with and without additional capital). Without the latter belief elicitation, the response to gender we identify in the capital allocation decisions could be consistent with a continuum of belief-based discrimination and taste-based discrimination (Bohren et al., 2023). The belief elicitation, which was incentivized for accuracy, thus allows us to determine the extent of each source of discrimination.<sup>5</sup> Each business application was evaluated multiple times, and

<sup>&</sup>lt;sup>4</sup>The application form was designed based on interviews with loan officers at both microfinance institutions and commercial banks. It provided no more information than what would be available in a typical loan application at an Ethiopian financial institution.

 $<sup>^{5}</sup>$ An alternative approach to identifying statistical discrimination is to vary the amount of information observed by the evaluator. However, Bohren et al. (2023) show that this method can only partially identify

each loan officer evaluated multiple businesses, resulting in a sample of 3,696 evaluations and an identification strategy that incorporates both business and loan officer fixed effects. This context allows us to study the key players of interest: real businesses interested in applying for capital, and loan officers that are regularly involved in making capital allocation decisions in the financial industry.

To assess the accuracy of the loan officers' beliefs and implications for profit maximization, we conducted a follow-up survey of the businesses 18 months after the competition. We compare the loan officers' subjective beliefs with actual future business performance to determine the accuracy of those beliefs.<sup>6</sup> We also use machine learning algorithms to evaluate whether a business owner's gender serves as an effective predictor for more profitable and successful businesses. The three components of our research design—loan officers' capital allocation decisions, their subjective beliefs, and business outcomes measured in the follow-up survey—allow us to identify the overall extent of discrimination (i.e., gender equity), separately identify taste-based and belief-based discrimination, and assess implications of capital allocation decisions for profit-maximization (i.e., targeting capital towards high-performing businesses).

We find no evidence that the loan officers discriminated against female-owned businesses. Randomly assigned business-owner gender did not affect loan officers' scores for awarding the competition prizes or their decision to forward the business to their own financial institution for consideration for a loan. The point estimates of gender differences in both decisions are small: less than .03 standard deviations in the competition score and less than .01 percentage points in sending applications to their own lending institution. We find no evidence for discrimination in any subset of the sample (e.g., based on characteristics of the business owner, the business, or the loan officers), and our standard errors rule out any meaningful differences in these

the source of discrimination. More generally, (Bohren et al., 2023) illustrate that elicitation of subjective beliefs is critical to identifying the source of discrimination as other methods generally require relatively strong assumptions.

 $<sup>^{6}</sup>$ See Bohren et al. (2023) for a review of the limitations of alternative standard methods of identifying the source of discrimination, such as comparing gender differences in capital decisions by loan officers to the true distribution of business performance by gender and estimating how discrimination changes as a function of information.

capital allocation decisions by gender.

Consistent with this lack of gender discrimination, we find that the loan officers expected similar future business performance and returns to capital (i.e., future survival, profits, and assets) for both genders. Loan officers also reported no gender difference in loan repayment likelihood. Coupled with the capital allocation decisions, this demonstrates that loan officers exhibit no preference-based partiality and no belief-based partiality. The alignment between capital allocation decisions and expectations of business performance is consistent with a model of decision-making based on beliefs: loan officers do not believe that business-owner gender is predictive of business performance, and so do not award capital differently.

We then turn to the accuracy of beliefs. Our follow-up survey showed that loan officers' beliefs about gender differences in future business performance aligned with actual average gender differences. Furthermore, just like the loan officers, standard machine learning algorithms do not prioritize gender in a set of optimal predictors of actual business profits measured 18 months after the competition. Rather, both the loan officers and our machine learning algorithms rely on other information in the application to target high-performing businesses.<sup>7</sup> This set of results implies that the loan officers have accurate beliefs and that there is no meaningful trade-off between gender equity and allocating capital to the highest-performing businesses. These results are consistent with the theoretical underpinnings of discrimination: theory suggests that if loan officers' beliefs are accurate and gender is *not* predictive of business performance, then discrimination would *not* be profit-maximizing.

We provide a number of checks to confirm the validity and robustness of our results. We show that the loan officers were attentive and thorough in their evaluations: capital allocation decisions responded to business characteristics in the application and were correlated with expectations of future performance, loan officers' beliefs and decisions were predictive of the actual future performance of the business, and business performance expectations were higher conditional on the business receiving additional capital. Moreover, our finding of a

<sup>&</sup>lt;sup>7</sup>Note that the application form was designed to provide the loan officers with the same type of information that would be used in making a decision on an initial loan application.

lack of discrimination is robust to a battery of tests that modify the identifying variation, variable definitions, and sample selection. We further assess the generalizability of our study, particularly to decisions on an initial loan application, using the SANS framework (List, 2020).

Our primary contribution is to provide compelling evidence that there is no gender discrimination in real-world capital allocation decisions, suggesting that it may not be a major contributor to gender gaps in access to capital. A few recent papers have used well-designed lab-in-the-field experiments to study gender discrimination in hypothetical business capital allocation decisions, framed as being for research or training purposes, in low- and middleincome countries (Alibhai et al., 2019; Brock and De Haas, 2023; Bartŏs et al., 2024).<sup>8</sup> In some cases, these decisions were made incentive-compatible by providing small bonuses for allocating hypothetical capital to businesses that performed well in the real world. These lab-in-the-field experiments have found evidence that there is gender discrimination on some margins and that it is concentrated among loan officers with biased gender attitudes and with less experience.

A key distinguishing element of our design is the high-stakes natural context: our experiment is the only one in which the loan officers' decisions influence the actual allocation of capital to real businesses. The decisions loan officers make in our experiment were designed to be equivalent to the decisions they make in everyday credit decisions at their institution. We do not find discrimination when studying these real decisions, which contrasts with previous evidence of gender discrimination in hypothetical contexts.<sup>9</sup> Using our data on beliefs, we can further rule out both statistical and taste-based discrimination.

<sup>&</sup>lt;sup>8</sup>Brock and De Haas (2023) conducted a clever lab-in-the-field experiment, framed as a training session, in which loan officers from Turkiye made hypothetical lending decisions for previous real loan applications in which business-owner gender was randomized. Loan officers received a bonus for approving loans that had performed well in the real world. Brock and De Haas (2023) do not find evidence for gender discrimination on the extensive margin (i.e., whether to approve a loan) and find that loan officers do not differ in their beliefs about loan repayment by gender, consistent with our findings. However, they do find that women receive stricter conditions on credit offers. This is similar to Alibhai et al. (2019), who find support for gender discrimination on the intensive margin by loan officers evaluating fictional loan applications in Turkiye. In Uganda, Bartos et al. (2024) also find that loan officers discriminate against individual female entrepreneurs on the intensive margin for start-up businesses but not against a team of two female entrepreneurs.

<sup>&</sup>lt;sup>9</sup>One recent exception is a concurrent study from the high-income country Chile that uses well-identified experimental variation in gender in a large field experiment and finds gender discrimination in the context of consumer credit (Montoya et al., 2020).

Prior to the recent experimental literature, the bulk of the previous literature relied on observational studies that estimate residual gender differences in survey data after controlling for observable characteristics. These studies have found mixed results, without a clear consensus on the existence of gender discrimination in business capital decisions.<sup>10,11</sup>

We build on this literature by identifying gender discrimination in business finance using experimental variation in a large-scale, high-stakes natural context. Our experimental approach improves upon observational studies where financial providers' incentives are strong, but gender discrimination is not well identified. Our high-stakes setting improves upon lab-inthe-field studies that yield convincing identification but often lack the strong incentives that loan officers face in the real world. To the best of our knowledge, our paper represents one of the first experimental estimates of gender discrimination in a real-world capital allocation decision that influences outcomes for real businesses.

An additional key contribution of our paper is to use financial providers' elicited beliefs to link their decisions to theoretical frameworks for discrimination. Previous research typically has not observed underlying beliefs, making our study one of the first to measure and estimate the accuracy of these beliefs across our entire sample. Bohren et al. (2023) show that comparing subjective beliefs with the true underlying distribution of outcomes is the best way to distinguish between sources of discrimination. Our incentive-compatible belief elicitation allows us to directly study whether loan officers' beliefs about gender and business performance align with their actual decision-making. Furthermore, by collecting data on true business performance, we evaluate the *accuracy* of these beliefs, the critical component to identifying whether gender discrimination is a profit-maximizing strategy that can persist in equilibrium. We do so by using a novel approach in which we benchmark beliefs against ma-

<sup>&</sup>lt;sup>10</sup>For example, Muravyev, Talavera and Schäfer (2007) find that female-managed firms are less likely to obtain a bank loan across 34 countries, primarily representing Central and Eastern Europe. In contrast, Aterido, Beck and Iacovone (2013) find that across Sub-Saharan Africa, the gender gap in using formal bank credit, and being rejected conditional on applying for a loan, disappears after controlling for the firm characteristics. Beck and Cull (2014) find some evidence that female-owned firms are more likely to have bank loans in Africa, likely reflecting survival bias. See Klapper and Parker (2011) for a more thorough review.

<sup>&</sup>lt;sup>11</sup>A related literature explores credit decisions when clients and loan officers share traits, which suggests that discrimination may be an underlying phenomenon (Fisman, Paravisini and Vig, 2017; Beck, Behr and Madestam, 2017).

chine learning algorithms (i.e., a "synthetic" judge for the competition). This comprehensive approach enables a deeper understanding of the interplay between beliefs, decision-making, and the implications of gender discrimination in the realm of business finance.

The rest of the paper proceeds as follows. Section 2 describes the context in which we implement our study and our experimental design, including our empirical strategy for identifying discrimination and differential beliefs. We present our findings in Section 3 and discuss the generalizability of these results in Section 4. Section 5 concludes.

## 2 Context and Experimental Design

#### 2.1 Ethiopian context

Ethiopia generally performs poorly on global indicators of gender equality. For example, in the World Economic Forum's 2016 Global Gender Gap Report, Ethiopia ranked 109 of 144. This low rank was driven by sub-indices related to labor and education outcomes: they ranked 106 on economic participation and opportunity and 132 on educational attainment. These stark gender differences suggest that gender discrimination (both belief-based and alternative mechanisms such as social norms or prejudice) may be present in various contexts in Ethiopia.

After the agricultural sector, the most common way women participate in the labor force in Ethiopia (and in Sub-saharan Africa) is as entrepreneurs. This highlights the importance of gender gaps in capital and business performance. Based on data from the Ethiopia Socioeconomic Survey, the World Bank (2019*a*) documents that male business managers are 3.7 percent more likely to borrow and borrow approximately 50 percent more than their female counterparts.<sup>12</sup> There is increasing acknowledgment of these gender gaps, which has driven policy responses. For example, Ethiopia has a financial inclusion policy that specifically targets gender gaps, and many lending institutions are encouraged to lend to female clients.

 $<sup>^{12}\</sup>mathrm{A}$  business manager is defined as an individual within a household in charge of the decisions regarding the earnings from an enterprise.

#### 2.2 The Business Plan Competition

In 2019, the Entrepreneurship Development Institute (EDI)<sup>13</sup> launched a business plan competition, EthioSpur, to provide capital and other awards to promising businesses. Business plan competitions are an increasingly common method to stimulate entrepreneurial growth in developing countries. For example, during the time of our own competition, we were aware of two other business plan competitions in Ethiopia itself.

The competition's prizes were 300,000 ETB, 220,000 ETB, and 140,000 ETB for the top three businesses.<sup>14</sup> In addition, the top 20 businesses were awarded with media and marketing coverage, and the top 100 were awarded with a "fast track to credit," as described in Section 2.5. The competition was promoted on a national level via social media, SMS, and targeted outreach by EDI staff.

To participate in the competition, business owners had to be the majority business owner in the business, be operational for at least four months, have a business license, and complete the application form.<sup>15</sup> Any business that would seek capital (including loans) from a formal financial institution would meet these minimal requirements (discussed in Section 4).

We partnered with EDI to study whether loan officers recruited to judge the competition discriminated against female-owned businesses during the judging process. In an approach similar to an audit study, recruited loan officers were given a packet of applications to evaluate in which the gender of the applicant had been randomly assigned.

We intentionally designed the application form to collect the same information loan officers use to make initial decisions on loan requests in their financial institutions. We interviewed financial providers from nine different financial institutions on their criteria when evaluating

<sup>&</sup>lt;sup>13</sup>The Entrepreneurship Development Institute, formerly Entrepreneurship Development Center, is a key agency tasked by the government of Ethiopia to increase entrepreneurship and economic growth, with specific attention to the needs of women entrepreneurs. A key element of EDI's mission is to improve access to finance.

<sup>&</sup>lt;sup>14</sup>This corresponds to approximately 9,375, 6,875, and 4,375 USD at the time of the competition. These amounts are within the range of expected loans for smaller businesses. For example, in Alibhai (2021), a dataset of 357 female entrepreneurs interested in borrowing from Wasasa MFI in Ethiopia, the median loan request was 200,000 ETB.

<sup>&</sup>lt;sup>15</sup>Businesses were not required to have a license at the time of the application, but were informed that they would be required to get a business license to receive any prizes.

businesses and reviewed their standard loan application forms. We then used these as a template for the competition application. The application form collected information on current business characteristics (e.g., industry, profits, years of operation, etc.) and a business expansion plan (e.g., description of plan, how awarded funds would be used, expected revenue). The form also collected additional information on the business owner (e.g., marital status, age, gender).<sup>16</sup> As in a loan application, the information on the application was self-reported. To ensure that applicants were truthful, they were informed that all information would be audited and verified for winning businesses. If a business was found to have provided false or misleading information, it would not only be disqualified from the competition, but also from all future EDI initiatives. The application was designed to be simple and available in multiple languages, and the application could be submitted online, in hard copy, or via email.

#### 2.3 Applicants

The competition attracted 916 businesses. Table 1 provides summary statistics on the median business performance of the applicants, overall and by business owner gender. The median years in the industry is 5 years for both male and female businesses. The median profit for the previous month is 15,000 ETB (500 USD), the median number of employees is 3, the median value of assets is 240,000 ETB, and the median value of liabilities is 4,000 ETB. This profile reflects the type of business that we expect to apply for capital. For example, our sample is similar to that in a previous study of female loan applicants at Wasasa Microfinance Institution: their median monthly business profit was 15,000 ETB, median number of employees was 1, the median age of the business was 4 years, and the median value of reported assets was 150,000 ETB (Alibhai, 2021).<sup>17</sup> Below the median, we report the mean and standard deviation. The mean is generally much higher than the median, highlighting a significant right tail of larger businesses that applied to the competition. Relative to male businesses, we

<sup>&</sup>lt;sup>16</sup>The complete application form can be found in Appendix A.

<sup>&</sup>lt;sup>17</sup>We are not aware of a more comprehensive representative sample of loan applicants in Ethiopia to which we can compare our sample. We take the similarity in our sample and that of the study at Wasasa MFI as support that our sample overlaps well with our population of interest: businesses requesting capital.

find that female-owned businesses report lower profits, have fewer employees, and have fewer assets and liabilities. Only the profit gap is statistically significant. Section 3.3 discusses the relevance of this gender gap in more detail.

Table 1 illustrates that most businesses that applied to the competition are relatively small but more successful and larger than the median Ethiopian business. Note that gender gaps in credit are evident even among larger businesses in Ethiopia (World Bank, 2024). In our own sample, female-owned businesses were equally likely to apply for loans in the past year (32.5 percent), but were six percentage points less likely to receive them, conditional on key business characteristics.

Table 2 provides summary statistics for the business owners. 44 percent of applicants were female-owned businesses. The sample is highly educated: nearly 50 percent have a bachelor's degree or higher, though this varies by business owner gender. Female-owned businesses similarly have more children (1.95 vs 1.62), though gender differences in marital status are smaller (54 percent are married or cohabitating). Both genders report high levels of being a household head (86%) and a high self-reported risk preference (8.64).<sup>18</sup>

#### 2.4 Loan Officers as Judges

The competition was judged by loan officers recruited from lending institutions (i.e., banks and microfinance institutions) across Addis Ababa. Institutions were asked to provide experts who met the following criteria: (i) involved in reviewing applications seeking capital from the institution, with specific attention to urban clients, capital for business purposes, and individual applicants or enterprises;<sup>19</sup> (ii) employed as a loan officer or a member of the loan approval committee; and (iii) employed for at least one year at the institution. These criteria aimed to ensure that those recruited were from the relevant population for reviewing requests for capital. Thus, just as applicants were real businesses interested in growth and capital,

<sup>&</sup>lt;sup>18</sup>This includes sharing the status of the household head with a spouse.

<sup>&</sup>lt;sup>19</sup>This is in contrast to "social collateral" loans in which a group receives a loan with joint liability, commonly found in microfinance.

judges were real experts who reviewed and evaluated loans for businesses as their primary profession.

The recruited loan officers spanned 13 different lending institutions, representing a significant portion of the institutions in the financial sector serving Addis Ababa. 14 percent were female and 65 percent were recruited from microfinance institutions. On average, the loan officers had been at their respective institution for five years, and in finance for 11 years.

Loan officers reviewed applications and completed evaluation forms remotely. Due to COVID-19, their orientation was conducted via phone. It covered all questions in the evaluation form, signing a contract, and a "comprehension check" in which they were explicitly asked about how the information in each section of the evaluation form would be used.<sup>20</sup> This ensured that the loan officers understood the definitions and objectives of each question. To

<sup>&</sup>lt;sup>20</sup>The contract included agreeing to undertake "to perform the services with the highest standards of professional and ethical competence and integrity," reviewing the expertise requirements of a judge, remuneration (including the bonus based on the accuracy of beliefs described in Section 2.5), and non-monetary benefits (recognition on both EDI's website and at the awarding event for the competition).

avoid social desirability bias, the loan officers were not told ahead of time that their evaluations would be used in a study on gender and finance or that they were participating in an experiment. All communication with the loan officers, including the orientation, was conducted by the local project manager blinded to the key question of interest and the randomized gender assignment. The loan officers were compensated 2,500 ETB for their time upon satisfactory completion of their evaluations within two weeks, though extensions were granted.

The recruitment process highlights that these loan officers had several incentives to conduct a thorough and thoughtful review, in addition to payment contingent on quality. They had been handpicked by their respective institutions to serve as judges, in some cases based on formal Memorandums of Understanding (MoUs) between EDI and their institutions. EDI is a highly respected agency in Ethiopia with a key focus on developing and maintaining relationships with many of the financial institutions that provided the judges. Thus, there would be a reputational consequence both within their institution and in the broader financial sector for poor performance on the task. In Section 3.2, we provide evidence of the quality of their evaluations.

#### 2.5 Evaluation Form: Treatment Salience and Outcomes

*Treatment Salience:* The loan officers reviewed digitized application forms that were translated into English and shown in a standard format.<sup>21</sup> Appendix Figure A1 shows an example of an application form, with identifying information redacted. The top of the form provided demographic information about the applicant, including gender. The remainder of the form showed information about the business and the business plan.

The evaluation form that the loan officer completed for each reviewed business was divided into four sections (see Appendix Figure A2). Section A was designed to ensure the salience of the randomly assigned gender without revealing the research question. This section asks the loan officer to confirm the basic demographics of the applicant: ID, age, gender, total years

 $<sup>^{21}</sup>$ An exception to the translation requirement was made for detailed business plan narratives submitted in Amharic, the most prevalent local language in Ethiopia.

of experience, and whether the applicant was also employed outside of the business. The loan officers were informed that this section was used to verify that the correct application was being reviewed. In addition to ensuring that the evaluator was aware of the randomly assigned gender of the business owner, we used this section to check that the loan officer was paying attention to the information in the application. 98.5% of evaluations noted the gender correctly.

To confirm that gender was not revealed in other parts of the application, our local survey firm explicitly reviewed the digitized application materials and confirmed that there was no information in any digitized form that would reveal the gender of the applicant. In addition, in the sample of applicants, both genders are represented across all twenty industry categories included in the application form, suggesting that the industry alone would not reveal the gender of the applicant. Similarly, EDI was not concerned that businesses were gendered to the extent that the type of business would reveal the true gender of the business owner or cast doubt on the credibility of the randomly assigned gender of the business owner. This suggests that any observed gender discrimination would likely not be due to the business owner's gender being revealed or surprising.

#### Beliefs on Future Performance:

Section B asked the loan officers to provide a prediction of the business' performance in January 2021, exactly one year after the submission of applications. Importantly, the majority of the evaluations were completed only a few months prior to January 2021. As a result, the loan officers were well aware of the shocks in the economy, including those related to the COVID-19 pandemic, at the time of their predictions. They were asked to provide these predictions for two scenarios: if the business did or did not win 300,000 ETB (i.e., the amount of the top prize) from the competition. The loan officers predicted the likelihood of survival, monthly profit, capital stock, and number of paid employees in these two scenarios.

Our interviews with loan officers indicated that a business's future profitability is a key metric for deciding whether to allocate capital to a business at their institution. Loan officers said they aim to allocate loans toward more promising businesses, in part because the probability of repayment and returns to capital is increasing in business performance. In an exit survey of 43 loan officers who served as judges, 86 percent reported that growth potential (i.e., future profits) was either an important or very important factor when determining whether to approve a loan. We also asked the loan officers explicitly about the likelihood of repayment for a 3-year loan for 100,000 ETB.

This section on beliefs was incentivized for accuracy. The loan officers were informed that the person with the most accurate evaluations for Section B would receive 15,000 ETB (500 USD). We intentionally did not provide details on how accuracy is determined for the bonus, consistent with Danz, Vesterlund and Wilson (2022) who find that false reports of beliefs are *lower* when subjects are simply told that the payment rule is designed to maximize their payment, rather than being given additional information of the details of the incentivecompatible payment calculation.<sup>22</sup> We similarly chose to have one large bonus, following the guidance from Charness, Gneezy and Halladay (2016) that randomly paying a large amount to one subject is as effective as paying a smaller amount to every subject. A conservative interpretation of our approach is that the loan officers' perception of our belief elicitation is equivalent to simply asking them for their best prediction. Charness, Gneezy and Rasocha (2021)'s review of the literature finds that such introspective belief elicitation performs equally well as "state-of-the-art" complex belief elicitation methods (e.g., quadratic scoring rule). This is particularly true with respect to accuracy, the extent to which elicited beliefs match the objective probabilities of an event, which is the purpose of our belief elicitation (Trautmann and van de Kuilen, 2014). Charness, Gneezy and Rasocha (2021) conjecture that increasing

<sup>&</sup>lt;sup>22</sup>Danz, Vesterlund and Wilson (2022) compare false reports of subjects' beliefs when they are told "the payment rule is designed so that you can secure the largest chance of winning the prize by reporting your most accurate guess," to a treatment arm in which in addition to the statement, they were also given details on how the binarized scoring rule, a state-of-the-art elicitation, is calculated. Similarly, Charness, Gneezy and Rasocha (2021)'s review of the literature highlights that in most cases where complex scoring rules that are incentive-compatible to truth-telling are used, subjects are also explicitly told by the researchers that telling the truth will maximize their payment. This further suggests that the effectiveness of incentive-compatible structures may be driven by respondents responding to the researchers' claim that truth-telling maximizes payment.

simplicity is an important dimension for improving belief elicitation.<sup>23</sup>

We elicit the beliefs of loan officers on future business performance to determine the extent of each source of discrimination. Common methods used to determine the source of discrimination that do not incorporate such belief elicitation are generally limited and require strong assumptions. For example, (Bohren et al., 2023) highlight that any response to gender in the capital allocation decisions will be consistent with a continuum of belief-based discrimination and taste-based discrimination. In addition, the common method of comparing loan officers' decisions to the true distribution of business success cannot disentangle inaccurate beliefs from partiality, and estimating how discrimination changes as a function of the information provided can only partially identify the source of discrimination. Thus, elicitation of loan officers' beliefs is a necessary measure to effectively determine sources of discrimination.

The loan officers were also informed that their responses in this section would have no bearing on the awarding of the capital from the competition.<sup>24</sup> Because we analyze beliefs as a mechanism underlying capital allocation decisions, we designed the evaluation form to allow for independence in the decision-making process between providing beliefs on business success and capital decisions. In this way, we ensured that loan officers had no incentive to manipulate their stated beliefs about business performance in order to influence capital allocation outcomes.<sup>25</sup>

Capital Allocation Decisions: Section D was the loan officer's overall score for the business that was used to determine the competition's prizes. The loan officers were asked to score

<sup>&</sup>lt;sup>23</sup>In general, there are two primary concerns with non-incentivized introspection: resorting to defaults or random responses, or explicit bias in reporting due to factors such as experimenter demand effects (Charness, Gneezy and Rasocha, 2021). In terms of the former, we show in Section 3.2 that elicited beliefs are both predictive of future performance and responsive to baseline information, confirming that the loan officers did not respond randomly. Section 3.2 provides evidence for the loan officers being thoughtful and attentive in their evaluations. In addressing the latter concern, Section 4 details the limited role of experimenter demand and social desirability biases in our context.

<sup>&</sup>lt;sup>24</sup>In the orientation, the loan officers were told that "this information is collected to understand what characteristics determine business success. We are collecting information from experts, such as yourself, since you are best equipped and knowledgeable to predict a business's success."

<sup>&</sup>lt;sup>25</sup>Our incentive structure ensured that the loan officers did not face any external incentive to align their stated beliefs with their capital allocation preferences. However, we would not expect the outcomes themselves to be independent. For example, if a loan officer perceives a business as more likely to succeed, we would naturally expect they may prefer to allocate capital to it, particularly for loans.

the business on overall impression, value proposition, and entrepreneurial credibility with a range of 1 to 10 each. This was then aggregated into a final score using the following formula: FinalScore = OverallImpression + .5 \* (ValueProposition + EntrepreneurialCredibility).Importantly, the loan officers were informed that this was the only measure that would determine the competition's winners.

Following Section D, the loan officers were asked whether they wanted the applicant's information to be sent to their institution for consideration for a loan. This question served as a proxy for capital allocation decisions from the provider's own lending institution, particularly for decisions on the initial application for a loan request.

Identifying promising businesses as potential borrowers was a key part of discussions with lending institutions when forming partnerships for the competition, beginning with the initial recruitment of loan officers from lending institutions to serve as judges. Several institutions signed MoUs that explicitly committed the lending institution to provide identified applicants with a fast-track loan process.<sup>26</sup> Thus, the leadership at lending institutions was aware from the start of their involvement that identifying potential borrowers and facilitating access to loans was of key interest. Similarly, in the orientation for recruited loan officers serving as judges, they were informed that EDI would "let your institution know you recommend this person to be reviewed for a loan and forward this information to your institution if the applicant is interested in a loan." Hence, the decision to forward the applicant to their own lending institution was a meaningful proxy for that institution reviewing the applicant as a potential borrower.

Our main outcomes of interest for capital decisions are 1) the loan officer's final score from Section D, and 2) whether they requested the applicant's information be sent to their own institution for consideration for a loan.

<sup>&</sup>lt;sup>26</sup>Though MoUs may not be easily legally enforceable in practice, they are meaningful agreements. This is supported by the fact that the institutions took time and negotiation to reach an agreement, the agreements differ by institution, and not all institutions were ready to make such a commitment. Ultimately, because of the disruptions caused by COVID-19 in the interim and the delays in the judging process, EDI did not track what happened to promising businesses after they were forwarded to the lending institutions. However, loan officers and lending institutions would have considered their decisions consequential when they were making them as they would not have known that EDI would not follow up with applicants.

Additional components in the evaluation form: Section C collected additional information about the loan officer's beliefs about the business owner. They were asked to evaluate the business owner's managerial skills, sources and amount of capital for the business, market demand for the business, and whether the business was the primary source of income for the household. This section was not incentivized. It was designed to shed light on potential beliefs that did not affect business performance but could be influenced by gender and affect an evaluation of a business.

#### 2.6 Random Assignment

We created duplicates of the original applications so that each application would be shown at least once as a male-owned business and as a female-owned business.<sup>27</sup> We then randomly assigned those applications to be shown as either male or female to each loan officer, in a random order, with each loan officer receiving 48 or 49 application forms (referred to as their "application packet").<sup>28</sup> Each application was reviewed multiple times with a randomly assigned business owner gender, and each loan officer evaluated multiple applications. Appendix Figure A3 illustrates that the median number of reviews per business was 4, and the median number of evaluations completed by a loan officer is 48.

Due to COVID-19, there was a delay between the submission deadline to the competition and the evaluation process, and the evaluation process itself took longer than planned. The competition closed on January 20, 2020, and evaluations were conducted from September 2020 to December 2020<sup>29</sup>. Thus, the loan officers were aware of COVID when they scored the applications and predicted business success. Loan officers benefited from the delay because they had more contextual information to predict business performance in January 2021, given information on past business performance in January 2020.

 $<sup>^{27}</sup>$ Each application is duplicated two to eight times. The number of times they were duplicated was randomly determined, and the median number of reviews was 4.

<sup>&</sup>lt;sup>28</sup>If it was the case that an applicant was assigned to the same loan officer twice, we simply dropped one of the application forms before providing the packet to the loan officer.

 $<sup>^{29}\</sup>mathrm{A}$  few loan officers also returned packets after the December deadline.

#### 2.7 Estimating Equations: Identification of Gender Discrimination

We estimate whether capital allocation decisions differed when the business owner was randomly assigned to be shown as male using the following estimating equation:

$$Y_{ij} = \beta_1 * RandomlyAssignedMale_{ij} + \alpha_i + \alpha_j + \epsilon_{ij}$$
(1)

where RandomlyAssignedMale indicates that applicant *i* assigned to loan officer *j* was shown as a male. The specification includes applicant and loan officer fixed effects and uses robust standard errors.<sup>30</sup> We study two pre-specified outcomes that reflect capital allocation decisions. The first outcome is the overall final score given to the application, which determined the winners of the business plan competition. The second outcome is an indicator of whether the loan officer selected the business application to be forwarded to their institution for consideration for a loan.

We next estimate Eq 1 on a pre-specified set of loan officer predictions of future business performance in the upcoming months: survival, profits, and assets. We estimate these for the loan officer's beliefs on expected business performance with and without having received additional capital. We use the differences in these predictions as a measure of the loan officer's expectations on the return to capital as a function of gender.

We limit our primary analysis sample to evaluations in which the loan officers completed all our pre-specified outcomes. Our primary analysis sample consists of 3,696 completed evaluations of 916 businesses by 84 loan officers. In this sample, 910 businesses were evaluated by multiple (2 to 8) financial providers, and 83 loan officers reviewed multiple applicants (2 to 79). 82 of these loan officers had variation in the gender of the applications they reviewed.

 $<sup>^{30}</sup>$ Since applications are randomly assigned to loan officers, there is no need to cluster at the loan officer level (Abadie et al., 2023).

#### 2.8 Ethical Considerations

As in all audit study designs, our methodology uses deception by randomizing the gender depicted in the application that a loan officer reviews. The justification for using deception in audit studies is that no alternative method exists to rigorously identify discrimination, as was the case in our setting. Given the scarcity of studies identifying gender discrimination in business finance and low-income country settings, we argue that the benefits of the research justified the design. The study was approved by the IRB at UC Merced. It was also approved by the Entrepreneurship Development Institute, the local organization with whom we collaborated. EDI is a highly respected institution in Ethiopia and had a reputational stake in the study. All the loan officers who served as judges were debriefed and informed after the completion of the study that demographic information was manipulated for research purposes in the applications they were reviewing.

Another ethical concern with audit studies is the time experts spend reviewing fake materials. In our case, experts were evaluating real businesses for a real business plan competition, and they were compensated for their time.<sup>31</sup>

## 3 Results

#### 3.1 Identifying Discrimination

We find that the randomly assigned gender of the business owner did not affect capital allocation decisions by loan officers, neither for the capital prize in the competition nor for consideration of a loan at their own institution. Table 3, Column 1 finds that the final score, which was used to determine who would be awarded the competition prizes, is not statistically different whether the applicant was shown as male or female. In fact, when applicants were

<sup>&</sup>lt;sup>31</sup>An additional ethical concern is the scores given to the applicants for the business plan competition. If we had observed discrimination, there were two possible ways we would have proceeded: using only real gender or using only one gender when determining scores to award the competition prizes. However, since we did not observe gender discrimination, EDI chose to use all evaluations in determining the prizes.

Table 3: Causal Effect of Gender on Capital Allocation Decisions

\* p < 0.10, \*\* p < 0.05, \*\*\* p < 0.01. Score is the final score in the business plan competition, determined by Overall Impression (Overall Impress) + .5\* Value Proposition (Value Prop) + .5\*Entreprenuerial Credibility (Entreprenuerial). Each of these subscores is on an increasing scale of 1 to 10. Loan indicates whether the application was forwarded by the loan officer to their own institution for loan consideration. Specifications include loan officer and application fixed effects. Robust standard errors in parentheses.

shown as male, they received slightly lower scores. The point estimate for the difference in scores is 0.105 points (on a scale from 2 to 20), which amounts to a difference of less than .03 standard deviations. The 95 percent confidence interval for the differences in scores is similarly very small (-.337 to .127), a range of merely -.07 to .03 standard deviations. These results suggest that loan officers did not discriminate by applicant gender in the allocation of capital in the business plan competition. Columns 2 through 4 document differences in each component of the final score (each ranging from 1 to 10), and we continue to find no meaningful differences by randomly assigned business-owner gender.

We then study whether the loan officer wanted to forward the application to their own institution. Randomly assigned business-owner gender did not affect the loan officers' decision to send the applicant's information to their own institution for consideration of a loan (see Table 3, Column 5). We also explicitly asked the loan officers for their beliefs about the applicant's ability to repay a loan and find no significant difference in their expectations of either strategic default or default due to lack of resources based on randomly assigned business-owner gender.<sup>32</sup> The point estimate on the difference in the decision to forward the applicant

<sup>&</sup>lt;sup>32</sup>In 19 and 13 percent of evaluations, the loan officers believed the applicant would be unable to repay a loan or strategically default, respectively. Differences by randomized gender were .7 and .1 percentage points. The loan was described as being for 3 years for 100,000 ETB. This outcome was not a primary outcome in our pre-analysis plan and was only pre-specified conditional on loan consideration being uninformative.

Figure 1: CDF of Final Score by Randomly Assigned Gender

is less than .01 percentage points. This highlights that the loan officers did not discriminate even when making decisions relevant to their own institution.

The standard errors for both estimates are very small, allowing us to rule out any meaningful differences in how the application was treated as a function of the randomly assigned gender of the business owner. The similarities across both capital allocation outcomes suggest significant external validity across the two settings.

This lack of discrimination is consistent across the distribution of scores in the competition (Figure 1). The figure highlights that throughout the distribution of business quality, randomly assigned gender had no meaningful effect on the evaluation of the business. A Kolmogorov-Smirnov test finds no statistical difference between these two distributions, with a p-value of 0.639. Similarly, we find no differences in the variance of final scores by gender.<sup>33</sup> Note that the KS test also fails to reject the null of first-order stochastic dominance, indicating that the data is consistent with statistical discrimination alone (i.e., no taste-based

 $<sup>^{33}</sup>$ We test for differences in variance using the STATA command sdtest and robvar, reflecting the proposed tests by Levene (1960) and the alternative specifications proposed by Brown and Forsythe (1974).

discrimination), including no discrimination overall (Bharadwaj, Deb and Renou, 2024).<sup>34</sup>

We generally find no evidence of gender discrimination along several pre-specified dimensions of heterogeneity. We do not find discrimination conditional on the business owner's marital status, education, or number of children (see Table 4). We do observe gender discrimination against female widows for loan consideration. This is consistent with female widowhood signaling unique vulnerability and access to fewer resources.

We also find no evidence for discrimination conditional on business characteristics. First, we explore discrimination based on whether the business industry is male-dominated, a prespecified characteristic. If female business owners face discrimination in male-dominated industries, which tend to be more profitable, this could be an important driver of the gender

<sup>&</sup>lt;sup>34</sup>Bharadwaj, Deb and Renou (2024) propose that first-order stochastic dominance implies that taste-based discrimination must be present, i.e., that such a pattern in data cannot be supported by statistical discrimination alone.

Table 5: Heterogeneity by business performance

\* p < 0.10, \*\* p < 0.05, \*\*\* p < 0.01. Score is the final score in the business plan competition, ranging from 2 to 20. Loan indicates whether the application was forwarded by the loan officer to their own institution for loan consideration. Baseline profits are in units of 1,000,000 ETB. The number of employees is winsorized at the 99 percent level. Specifications include loan officer and application fixed effects. Robust standard errors in parentheses.

profit gap. We asked our local survey firm to have two employees review the products and services described in the application and categorize the business as belonging to an industry dominated by women, men, or neither.<sup>35</sup> Second, we present exploratory analyses based on business performance, as measured by profits and size. Even if there is no gender discrimination on average, if high-performing female business owners face discrimination, this could explain why they cannot grow further. We do not find support for discrimination within gendered industries using our survey firm's categorization of industries as female-dominated or male-dominated, nor as a function of business baseline profits or the number of employees (see Table 5).

In addition to testing for discrimination within subsets of business type, we also look for differences by whether the judging loan officer was employed at a microfinance institution

<sup>&</sup>lt;sup>35</sup>For each application, employees were requested to answer the following two questions with Yes, No, or Unsure: In your opinion, are over 90 percent of businesses that supply the main product described [in the application] run by women [men] (i.e., are over 90 percent of the business owners of such businesses female [male])? In practice, the employees categorized businesses as being dominated by a particular gender using a threshold lower than 90 percent. We use this question to define indicators for male or female industries for the businesses marked affirmative for each of these questions. 28 percent of applications were coded as female-dominated, 38 percent as male-dominated, 30 percent as unsure, and 3 percent as missing.

Table 6: Heterogeneity by loan officer characteristics

\* p < 0.10, \*\* p < 0.05, \*\*\* p < 0.01. Score is the final score in the business plan competition, ranging from 1 to 20. Loan indicates whether the application was forwarded by the loan officer to their own institution for loan consideration. MFI is an indicator for whether the loan officer was employed at a microfinance institution. Fem. Loan Officer is an indicator for whether the loan officer was female. Specifications include loan officer and application fixed effects. Robust standard errors in parentheses.

(MFI) or a woman. We find no heterogeneity in discrimination based on these characteristics (Table 6). Though MFIs often prioritize female clients, none of the MFIs that participated in the judging serve women exclusively. In our exit survey of loan officers (N = 43), no loan officer reported having a portfolio of borrowers of only one gender. The highest share of female borrowers in a loan officer's portfolio was 82.5 percent.<sup>36</sup>

By itself, these capital allocation decisions by the loan officers are consistent with a continuum of taste-based and belief-based discrimination. Consistent with a lack of belief-based discrimination, loan officers predict similar future business performance for applicants shown as male or female. As described in Section 2.4, the loan officers were asked to predict business performance one year after the application submission. Table 7 finds no difference in expectations of the business' profit (Column 1), survival likelihood (Column 2), or assets (Column 3) as a function of the business owner's gender. This lack of difference in expected business performance remains true for both predictions without additional capital (Panel A) and with

 $<sup>^{36}</sup>$ We pre-specified additional loan officer characteristics for heterogeneity tests based on information collected in an exit survey. However, our response rate on the exit survey was only 63 percent (43 loan officers); thus, we do not report these additional tests.

Table 7: Effect of Gender on Business Performance Beliefs

Female Mean	60.08	84.57	1089.4	

\* p < 0.10, \*\* p < 0.05, \*\*\* p < 0.01. Survival, Profits, and Assets are loan officer expectations with and without additional capital. Profit and Assets are in thousands of ETB. Survival is the probability of survival, from 0 to 100; Win. specifications winsorize the variables at 1 percent. Specifications include loan officer and application fixed effects. Robust standard errors in parentheses.

additional capital (Panel B).<sup>37</sup>

These results are robust to comparing the CDF of expected profits and assets by gender (see Figure 2). In each scenario and outcome, Kolmogorov-Smirnov tests fail to reject equality across the two distributions. We also find no differences in the variance of these distributions by gender, except for profit predictions in the condition with capital, where the variance in expected profits with additional capital is slightly higher among female-owned businesses.<sup>38</sup> Taken as a whole, the loan officers did not expect gender differences in a business's growth potential on average, even after receiving a capital infusion.

These results indicate that loan officers do not have belief-based partiality with respect to business owner gender. Combined with the lack of discrimination in capital allocation decisions, we can conclude that loan officers exhibit neither belief-based partiality nor preferencebased partiality (i.e., they do not engage in statistical or taste-based discrimination).

 $<sup>^{37}</sup>$ Appendix Table A16 finds no support for differences in the beliefs about return to capital by business owner gender. Appendix Table A1 includes beliefs on employment, an additional prespecified variable.

<sup>&</sup>lt;sup>38</sup>This difference in variance is not robust to using winsorized levels of profit expectations.

Figure 2: Distribution of Profits and Assets by Assigned Gender

We conducted an additional battery of pre-specified robustness tests that confirm the lack of discrimination: weighting evaluations so that each loan officer has equal weight (Table A4 and A5); controlling for the order in which evaluations were assigned (Table A6 and A7); using the gender as reported by the loan officer (Table A8); excluding 5 percent of loan officers with the least amount of variation in their final score (Table A13); limiting the sample to the first five applications given to the loan officer (Table A14); and removing loan officer fixed effects (Table A15). We also confirm robustness to limiting the sample to loan officers who passed various attention and internal consistency checks: correctly answering 75 and 100 percent of the verification questions (Table A9 and A10), application information predicted the final score with a p-value of less than .15 (Table A11), and prediction of profits and firm survival with capital were higher than predictions without capital (Table A12). The main finding of no discrimination in the evaluation of businesses is remarkably robust.

#### **3.2** Robustness of Evaluations

We provide several pieces of evidence that the loan officers were attentive and thorough when evaluating businesses. First, though randomly assigned gender did not affect evaluations, the loan officers did consider other aspects of the business when evaluating the applicant. Appendix Table  $A2^{39}$  shows that businesses with higher profits, greater assets, and business plans that projected greater employees and revenue were more likely to receive higher scores for the competition and to be forwarded to the lending institution. Evaluation outcomes are predicted by baseline business information, which indicates that the loan officers reviewed the businesses with effort and attention.

Second, the loan officers completed the initial verification section of the evaluation form with high accuracy. As described in Section 2.5, the loan officers were asked to verify the applicant's gender and other demographic characteristics before completing the evaluation. They correctly indicated the applicant's gender in 98.5 percent of evaluations, the applicant's age in 97 percent of evaluations, the applicant's experience in 96 percent of evaluations, and the applicant's employment status in 95 percent of evaluations.

Third, evaluations were internally consistent in several ways. The loan officers predicted businesses would perform better with capital than without in most evaluations. In 92 percent of evaluations, the loan officers predicted that the business would be as or more likely to be operational in a year if they received additional capital than if they did not. We observe similarly high percentages of internally consistent evaluations with and without capital for the projected number of employees (93%), capital stock (93%), and profits (84%).

Fourth, businesses with stronger predicted performance were more likely to be awarded capital. Appendix Table A3 finds that loan officers provided higher scores and were more likely to consider for a loan those businesses that they believed were more likely to survive, have higher profits, and have greater assets. Using our endline survey, we also confirm that both the final score and loan consideration decision were predictive of firm survival and profits

<sup>&</sup>lt;sup>39</sup>These estimations were pre-specified in our analysis plan.

18 months after the competition (Appendix Table A18).

Finally, loan officers had significant variation within their own evaluations, suggesting that they were thoughtful in evaluating the information in the application. The average range of scores used by a loan officer in their evaluations is 13.8 out of a possible 18, and the average standard deviation for final scores within a given loan officer is 3.6. Loan officers recommended 50 percent of their businesses for consideration for a loan, on average, and all loan officers except five forwarded at least one application to their lending institution. None recommended all of the businesses they reviewed to be considered for a loan.<sup>40</sup>

#### 3.3 Implications for capital targeting and accuracy of beliefs

A key contribution of our paper is to compare loan officers' decisions and beliefs with the actual gender gaps in business performance. Since loan officers did not discriminate by gender in their capital allocation decisions, if gender were meaningfully predictive of profits, this would suggest a trade-off between gender equity (i.e., the lack of gender discrimination) and profit maximization (i.e., targeting high-performing businesses). Comparing the loan officers' subjective beliefs with real future business performance also determines the accuracy of those loan officers' beliefs. Understanding this accuracy is crucial, as inaccurate beliefs affecting capital allocation have unique policy and welfare implications.<sup>41</sup>

In models of accurate statistical discrimination, the justification for discrimination is that considering gender can improve predictions about the future performance of businesses. That is, if financial providers have accurate beliefs that female-owned businesses perform differently, conditional on all other observable information, belief-based discrimination can be profit-

 $<sup>^{40}\</sup>mathrm{These}$  statistics are based on 83 loan officers that are used in our main sample and had more than 1 evaluation.

<sup>&</sup>lt;sup>41</sup>Some of the analysis in this section deviates from our original pre-analysis plan. This is because the original pre-analysis plan considered only statistical significance, as opposed to meaningful differences in the theoretical context of discrimination or differences across estimations. Nonetheless, we do report main outcomes from the original pre-analysis plan in Appendix Table A18 and A19, and provide explanations for the limitations of the original pre-specified analysis plans where relevant. In general, the analysis put forth in this section reflects a more accurate and precise analysis plan that maintains the purpose of the original. In addition, we do not conduct simulations on policies to reduce discrimination, as we did not find support for discrimination.

maximizing. In our case, loan officers' beliefs do not differ by business-owner gender. If these beliefs were accurate, this would imply that loan officers' lack of gender discrimination is consistent with targeting capital toward the highest-performing businesses. However, it may be the case that loan officers' beliefs are inaccurate, and business-owner gender truly has mean-ingful predictive value in identifying business performance. This would imply that the lack of gender discrimination in their capital allocation decisions (i.e., gender equity) comes at a cost of selecting lower-performing businesses (i.e., profit maximization). We assess this by connecting the loan officers' beliefs to real performance outcomes using endline measures of business performance, based on a follow-up survey of applicants 18 months after the competition.<sup>42</sup>

One of the most effective ways to test the accuracy of beliefs is to compare them to outcome data (Bohren et al., 2023; Manski, 2004). In our case, this is comparing loan officers' beliefs on future business performance with the actual gender difference in future business performance as measured in our follow-up survey. An OLS regression of endline business performance on business owner's gender and other business characteristics presented in the competition application<sup>43</sup> estimates that male-owned businesses were 2.85% (*standard error* = 2.35%) more likely to still be operational, earned 4,593 ETB (*standard error* = 2,364 ETB) more profit, and had 180,000 ETB (*standard error* = 130,900 ETB) more assets in our follow-up survey.<sup>44</sup> For all three outcomes, the real mean gender difference is within the 95% confidence interval of the loan officers' beliefs (Table 7). Thus, the direct comparison of subjective mean beliefs with mean outcomes suggests that loan officers' beliefs are accurate (i.e., fails to reject that the loan officers' beliefs are accurate).

The importance of assessing the accuracy of beliefs is that discrimination could be justified if decisions based on business owner gender lead to more effective targeting of capital toward higher-performing businesses. While beliefs were not statistically different from actual gender

 $<sup>^{42}</sup>$ Appendix Table A17 confirms that our main results on discrimination in capital allocation are robust to the sample for which we successfully survey at endline.

<sup>&</sup>lt;sup>43</sup>While loan officers had access to all of the business information in the competition's application, the regression for estimating the gender gap using the follow-up survey controls for only a subset of that information.

<sup>&</sup>lt;sup>44</sup>Consistent with the belief measures, these outcomes are also winsorized to ensure that both variables are treated in the same way and results are not driven by outliers.

differences in business performance, male-owned businesses tended to earn more profit than female-owned businesses. This raises the question of whether the gender gap in the true performance of businesses is large enough to justify discrimination. If it is, it would imply the loan officers' subjective beliefs meaningfully differ from the true gap, despite the difference not being statistically significant (i.e., the estimates are imprecise). We therefore examine whether the observed performance differences by business owner gender are substantial enough to warrant statistical discrimination. If they are not, we can conclude that the loan officers' beliefs were "accurate enough," as their beliefs did not result in a capital allocation decision that differed from what a model of accurate statistical discrimination would have predicted.

A statistically significant difference in profits by business-owner gender does not automatically imply that gender is an effective proxy for targeting more profitable businesses.<sup>45</sup> This is because using gender as a predictor may lead to overfitting, where gender appears predictive in sample data but does not reliably indicate higher profitability across different groups or future cases. Combined with cognitive limitations, the effectiveness of gender as a proxy depends on whether it provides stronger predictive value than other characteristics of the business.

We determine whether the gender gap is large enough to justify discrimination by assessing whether gender is an important variable when constructing an optimal prediction of business outcomes. One possible prediction model is simply an OLS regression of business outcomes on all information shown to loan officers. A crude measure of the predictivity of this regression is the  $R^{2.46}$  We can quantify the predictive value of gender by comparing the  $R^{2}$  in a regression with and without gender. Using a regression of winsorized endline profits on all quantifiable information shown to loan officers, including gender increases the  $R^{2}$  by only 1.9% (0.2447 versus 0.2401). This is consistent with the loan officers' beliefs being accurate: accounting for

<sup>&</sup>lt;sup>45</sup>Appendix Table A18 shows regression results estimating how business performance differs as a function of the true gender of the business owner, conditional on the business' capital allocation decisions by the financial providers. Appendix Table A19 estimates differences in gender on additional measures of business performance prespecified in the study's pre-analysis plan. Though we do not find statistically significant differences in the average likelihood of survival by business-owner gender, we do find that female businesses have lower profits even after controlling for financial providers' decisions. However, the magnitude is small.

<sup>&</sup>lt;sup>46</sup>Note that statistical significance is different from predictivity (Lo et al., 2015). Because the  $R^2$  is a measure of the distance between the values predicted by OLS and the true values in the sample, it is one possible measure of the predictivity of the model.

gender did not meaningfully improve model predictivity. However, a major concern with this naive linear regression is overfitting, where the model captures noise and random fluctuations in the data rather than the underlying relationship between the predictors and the outcome.

Machine learning methods aim to construct prediction models that reduce overfitting and thus minimize out-of-sample prediction error. A more robust way of quantifying the importance of gender is to use a machine learning algorithm to select optimal predictors of endline business profits. We consider the set of all quantifiable variables shown to the loan officers during the judging process and assess whether an algorithm will select gender as an important predictor from this set.

There are numerous potential algorithms for selecting optimal predictors of profits in this setting.<sup>47</sup> We provide results from three common methods (Athey and Imbens, 2019). We first use the least absolute shrinkage and selection operator (LASSO), which has been widely used for variable selection in linear regression models in the economics literature (Baylis, Heckelei and Storm, 2021). The LASSO introduces a penalty that shrinks coefficients in the regression model toward zero, producing a small set of predictors with non-zero coefficients. The purpose of this penalty is to prevent overfitting, reduce the risk of multicollinearity, and enhance predictive accuracy with a simplified model. The magnitude of this penalty influences the number of variables selected (i.e., models with larger penalties select fewer variables). We use 10-fold cross-validation to optimally select this penalty, a process that relies on randomly splitting the data into 10 subsamples and selecting the penalty parameter that minimizes out-of-sample prediction error.<sup>48</sup> This randomness implies that the variables selected may be slightly different each time the algorithm is implemented. Therefore, to assess the importance of gender as a predictor, we conduct 1,000 trials of the LASSO to see which of the 94 variables in the application the algorithm will select most often to target the most profitable businesses.

A drawback of the LASSO and other penalized linear regression methods is that variable

 $<sup>^{47}\</sup>mathrm{We}$  use profits winsorized at 99% as the target variable for all methods.

<sup>&</sup>lt;sup>48</sup>For each fold, the algorithm fits a linear regression on the remaining nine folds, then calculates the prediction error on the tenth fold. This is done for each fold, creating a mean prediction error across the ten folds for each penalty parameter  $\lambda_k$ . The algorithm then selects the  $\lambda_k$  that minimizes this prediction error.

selection can be unstable when many of the predictors are highly correlated, which is true in our setting (Zhao and Yu, 2006). Tree-based methods provide a more robust alternative (Athey and Imbens, 2019). These approaches recursively split the data into subsets based on values of the predictors (e.g., male versus female or above versus below a certain threshold), then estimate predictions in each subset. Each split aims to minimize the sum of in-sample squared errors across all subsets, and the average squared error reduces with each subsequent split. The subsets are called leaves, and the entire sequence of splits and subsets is called a tree. We provide results from two tree-based algorithms. The random forest averages over a large number of trees, where each tree is based on a bootstrap sample, and the splits at each stage are based on a random subset of the covariates that change every split (Athey and Imbens, 2019). Extreme gradient boosting (XGBoost) similarly averages over a large number of trees, but each sequential tree is designed to reduce the prediction error of the previous tree (Chen and Guestrin, 2016). Tree-based methods do not perform variable selection explicitly. However, it is possible to measure the contribution of each variable to prediction accuracy by calculating the reduction in the variance of the target variable (a proxy for prediction accuracy) when that variable is used in a tree split. This measure, known as feature importance, can be used to rank the variables.<sup>49</sup>

The results from the machine learning exercise, presented in Table 8, suggest that gender is not among the most important predictors of business outcomes. Panel A shows the variables most frequently selected by LASSO. LASSO tends to drop highly correlated predictors; consistent with this, the mean number of variables selected is 2.49, and only two variables are selected in over 50 percent of the 1,000 simulations. Gender is selected in just 5% of simulations. Panel B shows the top 5 variables in terms of feature importance in the random forest and XGBoost, as well as the importance and rank for gender. Gender ranks 52 in importance (out of 94 variables) in the random forest and 67 in importance in XGBoost.<sup>50</sup>

 $<sup>^{49}</sup>$ Tree-based methods tend to perform well "out of the box" (Athey and Imbens, 2019). Therefore, we use the default tuning parameters for random forest in Stata and XGBoost in R.

<sup>&</sup>lt;sup>50</sup>In an exit survey completed by a subset of the loan officers, they highlight current profits and growth potential as key criteria for approving a loan. These factors are also selected in Table A2, and randomly assigned gender does not affect expectations about growth potential (i.e., future business performance).

These results are consistent with the conclusion that loan officers' beliefs about gender are accurate: considering gender would not meaningfully improve their ability to target the most profitable businesses. As a result, there is no meaningful trade-off between gender equity and the targeting of successful businesses.

The machine learning exercise serves as a clear benchmark for loan officers' optimal capital allocation decisions. By design, the objective function of the machine learning algorithm is the same as the belief elicitation of the loan officers: to predict the business's future performance. Furthermore, the data used by the machine learning algorithm represents only a subset of the information available to financial providers (i.e., quantifiable information). Since the additional information observed by the loan officers is independent of gender by design, gender must be at least as informative in the machine learning context than in the decision made by the loan officers. Lastly, a large literature highlights that humans have limited resources when making decisions (i.e., limited attention).<sup>51</sup> Given these cognitive constraints, loan officers must rely on a limited set of criteria when making capital allocation decisions, while these constraints are less strict for machines. The fact that our machine learning exercise shared the same objective function as the loan officers, that loan officers saw even more information than the machine learning algorithm, and that machine learning is not restricted by human cognitive limitations collectively establish the machine learning exercise as a benchmark with which to compare the loan officers' decisions.

Comparing the machine learning predictions to loan officers' predictions demonstrates why loan officers did not discriminate despite the unconditional gender gap in profits. Just as our machine learning algorithm results selected key variables to identify successful businesses, loan officers also responded to key information about the business. The exercise highlights that the importance of gender in predicting business performance is dwarfed by the other detailed

 $<sup>^{51}</sup>$ Limited attention has been the subject of a large theoretical and empirical literature in economics; see for example, Sims (2003) and reviews by Wiederholt et al. (2010), Gabaix (2019) and Maćkowiak, Matějka and Wiederholt (2023). Lieder and Griffiths (2020) discuss how these models fit into the broader psychological literature on human cognitive limitations. Bartoš et al. (2016) discuss endogenous allocation of attention as an aspect of discrimination; we do not find evidence for this type of effect given that we document an absence of discrimination.
information provided in the application (and in a typical loan application more generally), even when there is a statistically significant difference in business performance by gender. If we consider the machine learning prediction model to be optimal, this suggests that loan officers' beliefs were not different enough from reality to affect how capital should be awarded.

Our results suggest that the loan officers' decisions are consistent with a model of decisionmaking based on accurate beliefs. Loan officers do not believe that gender predicts business performance, and in accordance with these beliefs, they do not discriminate. Moreover, our machine learning results suggest that the predictive value of gender is not large enough to justify statistical discrimination. This suggests that loan officers' beliefs are accurate enough to respond to gender in a manner consistent with profit maximization and that there is no meaningful trade-off between gender equity and targeting capital towards successful businesses.

# 4 External validity: Generalizability to the broader financial sector

We next discuss the generalizability of this study using the SANS framework (List, 2020). We posit that our results are informative about gender discrimination in capital markets in Ethiopia and directly generalizable to decisions about initial applications for loans and capital grants. We also consider the relevance of our findings to gender discrimination in low-income countries and business finance. The SANS framework offers a structured method for defining generalizability; as List (2020) points out, "all results are externally valid to some setting, and no result will be externally valid to all settings." The framework assesses generalizability through four factors: Selection, Attrition, Naturalness, and Scaling. If preferences, constraints, and beliefs in the research study align with those in the context of interest, then the findings can be generalized to that context. We focus on Selection and Naturalness. We have no Attrition by design: since applications were randomly assigned to loan officers, the randomized gender is necessarily orthogonal to loan officer attrition. Scaling is not applicable. Selection refers to the study group's comparability to the population of interest, and Naturalness refers to the naturalness of the choice task, setting, and timeframe—that is, the extent to which "the choice and outcome architecture [are] exchangeable between research and target settings" (List, 2020). Experimenter demand and social desirability bias are key aspects affecting naturalness. We address these two concerns directly, then categorize our study based on the stage of research in the general literature on the topic, which determines the weight of importance of the external validity assessment.

## 4.1 Experimenter Demand and Social Desirability

Our results are unlikely to be influenced by experimenter demand or social desirability bias, defined as motivations to please researchers or the competition host (EDI), respectively.

Experimenter demand is unlikely because loan officers were unaware of their participation in an experiment.<sup>52</sup> They communicated exclusively with a project manager who was blinded to the research question and randomized gender assignment.<sup>53</sup> Consequently, there existed no channel to induce experimenter demand.

Several factors suggest social desirability bias is unlikely to affect our results' generalizability to the broader financial sector. First, EDI's primary objective is to promote entrepreneurship in all sectors. While their mission includes supporting traditionally under-resourced populations, including women, a large segment of EDI's clients are male.<sup>54</sup> Broader mes-

 $<sup>^{52}</sup>$ The loan officers were simply told that "One of EDC's missions is to improve services and entrepreneurship growth by participating and conducting research. By participating as a judge in the EthioSpur Competition, you are consenting to share your contact information and de-identified responses with research partners who may use it to contact you for additional information and to conduct research." The loan officers were debriefed on the research after the competition was completed.

<sup>&</sup>lt;sup>53</sup>The project manager was not informed about the gendered randomization until necessary for debriefing the loan officers.

<sup>&</sup>lt;sup>54</sup>Note that EDI's focus on women has expanded since our study. This is because EDI, a new entity after our project, combines WEDP (a female-focused loan program) and EDC (the partner institution for this project at the time of the study). Other programs by EDC at the time of our study highlight their central focus on general entrepreneurship, with a sensitivity to the needs of underserved populations. For example, the Incubation Project, a contemporaneous initiative, was described on their website as follows: "the primary aim of this program is to develop innovative businesses that are being commercialized and be able to create sustainable profit to the owners, and create more jobs to the community." The only mention of women and youth was a statement saying they were eligible to apply.

saging and direct communication with lenders focused on identifying promising businesses without mentioning inclusive growth or women.<sup>55</sup> Individual loan officers did not appear to be familiar with EDI's programs, and none of the loan officers were aware of EthioSpur before their recruitment, indicating that they were unlikely to be familiar with EDI's mission statement. Second, the orientation provided loan officers with EDI's objectives for each evaluation question, none of which mentioned gender.<sup>56</sup> Prioritizing women or men to please EDI would imply pursuing an unstated objective at the cost of performing well on explicitly requested objectives. Third, the loan officers' responses in the evaluation forms, except for loan recommendations, were confidential and de-identified to all EDI staff and researchers, except for the project manager. Evaluation forms never captured the loan officers' names and were tracked through an ID number.<sup>57</sup> Fourth, if social desirability bias had affected responses, we might expect favoritism towards youth entrepreneurs, another under-resourced demographic group mentioned in EDI's mission statement. However, we do not find that loan officers favored younger entrepreneurs in any outcomes of interest.

Finally, each outcome was incentivized differently, yet our results are consistent across all three measures: monetary prize (beliefs), capital awarded by EDI (final score), and loans from one's own institution (loan consideration). If social desirability bias explained our results, it would imply an assumed priority of EDI influenced decisions across multiple domains, even when unrelated to EDI. The complete absence of messaging on women, explicit evaluation criteria, anonymity in evaluations, and consistent results across different objectives suggest social desirability biases are unlikely to explain our findings or affect generalizability.

<sup>&</sup>lt;sup>55</sup>This includes promotional materials, recruitment letters, orientation guides, contracts, and memorandums of understanding for the judging loan officers. For example, the partnership request to lending institutions describes Ethiospur as a business plan competition "to promote the entrepreneurial spirit and provide support to promising entrepreneurs with a strong passion to grow their business" and that loan officers are requested because "the expertise in your organization would be extremely valuable in the evaluation of the business plan competition applications...consistent with our existing partnership to promote entrepreneurs with significant potential."

<sup>&</sup>lt;sup>56</sup>For example, in the section on future performance beliefs, loan officers were informed that the information "this information is collected to understand what characteristics determine business success." Definitions were provided for each sub-category in the final score (e.g., "Value proposition: your overall assessment of the profitability potential of the applicant's business plan.").

<sup>&</sup>lt;sup>57</sup>Loan officers were informed their ID would be used to identify them if they won the bonus for evaluation accuracy. Even then, individual evaluations would remain anonymous.

In addition, EDI's focus on women in its mission statement is common in Ethiopia's financial sector. Lending institutions often emphasize inclusive growth, and during our study, Ethiopia had a national policy to improve women's financial access. Thus, any focus on women aligns with the broader financial sector's goals.

## 4.2 Selection

*Applicants*: EthioSpur recruited businesses seeking capital, similar to those supported by formal financial institutions through loans. The competition's information collection and eligibility requirements mirrored initial loan applications, ensuring relevant businesses participated. Among our sample, 32 percent had applied for a loan in the past 12 months, and 88 percent were interested in obtaining a loan through the competition, confirming their interest in capital, including loans. This interest highlights their relevance for understanding loan officers' beliefs and behaviors.<sup>58</sup> Additionally, the applicants' business characteristics are similar to those in the only other dataset of potential borrowers in Ethiopia, as discussed in Section 2.3 (Alibhai, 2021). The competition's minimal eligibility requirements mirrored initial loan applications, ensuring no business interested in seeking capital was excluded.<sup>59</sup>

In summary, our participation requirements mirrored initial loan requests, making the sampling process similar to typical loan applicants. By focusing on active entrepreneurs, our sample aligns with the core demographic of lending institutions, ensuring relevance to the broader financial sector.

Loan Officers: The loan officers who judged the competition were real experts from diverse banking institutions in Addis Ababa, including microfinance institutions and commercial banks. There was no indication that selection into the loan officer sample was correlated with

<sup>&</sup>lt;sup>58</sup>No significant gender differences were observed in loan applications in the past 12 months, interest in loans through the competition, or the amount of capital requested. Kolmogorov-Smirnov tests also found no statistical difference in the distributions of the amount requested by gender.

<sup>&</sup>lt;sup>59</sup>This includes the four-month operational history requirement. Sample loan application forms and loan officers emphasized the importance of business history, even for start-ups. For example, in the Wasasa MFI sample, over 80 percent of loan applicants reported using their own or partner's savings as starting capital, with less than 1 percent reporting a loan from an MFI and none from formal financial institutions. This indicates that businesses seeking capital generally have some operational history (Alibhai, 2021).

gender attitudes. The eligibility requirements ensured the sample was relevant to those making capital decisions in the financial sector. Thus, both the businesses and loan officers were sampled from the key population of interest.

*Experimental Variation of Business Owner Gender*: A key consideration is whether altering the gender of business owners changed the distribution of gender-incongruent businesses. For example, female-owned businesses in male-dominated sectors might appear more frequently in our sample than in the population. This could affect the applicability of our findings to real-world scenarios with a stronger correlation between business owner gender and business type. Our results suggest this is unlikely. Reduced generalizability would require loan officers to treat gender-incongruent businesses differently, i.e., evaluating female or male-owned businesses differently in a sector dominated by the opposite gender. Table 5 shows no such heterogeneity. This indicates the experimental manipulation did not inhibit generalizability. Both genders are represented across all 20 industries listed in the application form, and EDI did not believe gender incongruities would impact result interpretation.

## 4.3 Naturalness

We next assess the naturalness of our three key outcomes: beliefs, competition score, and loan consideration. Having addressed social desirability and experimenter demand, we focus on the naturalness of the setting and the similarity of the decision environment to a loan application.

We designed the competition's application form to mirror the criteria used by loan officers for initial capital lending decisions. Like a loan application, the information was self-reported but subject to future verification. This ensured that capital allocation decisions in the competition were based on the same information typically available to loan officers.<sup>60</sup> Since statistical discrimination models suggest discrimination arises from the informational value of gender, the observed lack of discrimination may be because loan officers had sufficient information about the businesses, reducing the need to rely on gender. The similar information environ-

 $<sup>^{60}{\</sup>rm We}$  interviewed financial providers from nine institutions and reviewed their standard loan application forms to design the competition application.

ment in the research and initial loan applications implies this lack of statistical discrimination is generalizable to credit markets.

One key outcome is beliefs about gender and future business performance, which were independent of all other outcomes and incentivized for accuracy. There was no aspect of the research design that altered loan officers' beliefs about business success. Another key outcome is the competition score. This was the natural decision for the business plan competition, determining the grant awards and thus directly generalizable to such decisions. Thus, the research design has no aspects that would change the preferences, constraints, and beliefs about future business performance or who deserves capital grants.

Another consideration for generalizability is whether loan officers make different decisions for loans versus grants or when acting for their employer. The loan forwarding decision addresses this concern and serves as a proxy for the decision to approve an initial loan application. This proxy is generalizable as long as: 1) the two measures are correlated, and 2) the relationship between the two measures does not differ by business owner gender. On the former, the two outcomes are mechanically correlated—to accept an initial loan application from the applicant, the loan officer must have access to their information. On the latter, our results suggest no gender discrimination in deciding to forward to the lending institution.

It is illustrative to consider an example that might raise concerns about the generalizability of the loan forwarding decision. Suppose loan officers have a quality threshold for forwarding an applicant, which is lower than for initial loan approval. If female-owned businesses are closer to this threshold, the conversion from forwarding to approval would be lower for women, limiting generalizability to initial loan decisions. However, we find no support for this. Among forwarded businesses, loan officers' beliefs about future performance and competition scores do not differ by gender, suggesting female-owned businesses are not closer to the threshold. Since perceptions and evaluations are similar by gender, gender should not affect the conversion from forwarding to initial loan approval. Note that the lower threshold for forwarding alone does not reduce generalizability. Thus, the causal effect of business-owner gender on the forwarding decision is a reasonable proxy for initial loan application approval to proceed to the next review step.

# 4.4 Wave Consideration: The Weight of External Validity and Boundaries of Generalizability

The framework in List (2020) highlights that expectations for external validity depend on the stage of the body of research.<sup>61</sup> We view our results as a Wave 1 insight for gender discrimination in low-income countries, establishing initial causality. Few studies have convincingly isolated causality using randomized gender in low- or middle-income country contexts. For gender discrimination in business finance, we see this study as contributing to Wave 2, understanding underlying mechanisms and exploring boundary conditions. In Wave 1, List (2020) argues that external validity is "extra credit," while in Wave 2, studies should vary subject populations, stakes, and other theoretically important factors to mirror natural settings.

A useful benchmark is the ideal experiment and its feasibility. To study gender discrimination in credit markets, the ideal experiment would randomize the business owner's gender in a loan application and follow the evaluation through the entire loan process. This is nearly impossible in most low-income countries. In Ethiopia, loan processes are conducted in person, and loan files are extensive and not digitized. Only one concurrent study has followed subjects through an entire loan process using a correspondence methodology in a high-income country with entirely digital applications and approval (Montoya et al., 2020). Given these limitations, designing a study in a low-income country closer to a natural context than our approach would be very difficult.

Theory provides guidance on the generalizability of gender discrimination in later stages of a loan review process. Our context is similar to the early stages, but capital requests often involve further steps and interactions where gender discrimination could become a fac-

 $<sup>^{61}</sup>$ List (2020) categorizes research stages into three waves: the first wave is efficacy and proof of concept, the second wave is underlying mechanisms, boundaries, and replications, and the third wave is measurement, mechanisms, and scaling.

tor. Loan processes typically include multiple visits and communications between a business and the lending institution. However, standard economic models of discrimination, including statistical, taste-based, and gender norm violations, suggest discrimination should be less likely at later stages. Models of statistical discrimination predict that more information reduces reliance on gender as a signal (Aigner and Cain, 1977; Guryan and Charles, 2013). Each interaction increases information, reducing statistical discrimination. For taste-based discrimination or gender norm violations, backward induction suggests a loan officer would not start a process likely to fail due to their preferences. Whether this prediction holds true is an open question for future research, both in terms of its existence and reconciling it with the lack of discrimination observed in early stages.

## 4.5 Lessons from the literature

Our paper contributes to the growing literature using experimental variation to study gender discrimination by loan officers in low- and middle-income countries, which has found discrimination in some contexts and margins of business credit. We discuss key factors that may help reconcile our findings with this previous literature: information, stakes, and contextual differences in gender norms. We also discuss what these mechanisms imply about when to expect discrimination.

We focus on three closely related experiments that found evidence for gender discrimination in low- and middle-income countries. Alibhai et al. (2019) presented Turkish loan officers with four fictional loan applications (two male-owned, two female-owned) and found they allocated less hypothetical money to female-owned businesses. Also in Turkiye, Brock and De Haas (2023) had loan officers review real loan applications previously processed by their bank, with gender randomized. They made two hypothetical decisions: loan approval and guarantor request. Only the former decision was incentivized based on the loan's real-world performance. They found no gender discrimination in (incentivized) loan approval but did find it in guarantor requests. Bartos et al. (2024) in Uganda had loan officers evaluate real start-up pitch decks, with randomized gender of the founder and CEO. Loan officers received a small endowment to "invest" in the start-ups they reviewed, with returns based on the businesses' real performance two years later. Loan officers invested less in single-owner female-owned start-ups and were less likely to select them as the best business.

Statistical discrimination models predict that gender discrimination is less likely to be found in contexts with more information. Evidence in the four experiments is consistent with the idea that the amount of information provided in loan applications may reduce discrimination, as in our study. Although we lack random variation in missing information, we find evidence of discrimination when all key pieces of information were missing: loan officers were 13.7 percentage points more likely to recommend male-owned businesses for a loan, a result statistically significant at the 5 percent level.<sup>62</sup> Brock and De Haas (2023) provided a similar level of information to our experiment and found no gender discrimination in the incentivized measure of loan approval. In contrast, Alibhai et al. (2019) used less detailed fictional applications, and Bartös et al. (2024) evaluated start-up pitches with no business track record. This suggests gender discrimination may be important in accessing start-up capital, where there is mechanically less information about a business's success, but it is less likely to explain the persistent gender gap in financing for existing businesses aiming to grow. Since existing businesses represent the majority of credit demand, the information mechanism suggests that we may not expect widespread discrimination in credit markets.

Another key factor is the stakes of the decisions made by loan officers. Standard models suggest taste-based discrimination, including norm-driven biases, decreases as costs increase and can disappear at high costs (Becker, 1957). Previous studies that found discrimination among loan officers use small or no payouts. Brock and De Haas (2023) only found discrimination on a margin that they did not incentivize. In contrast, the high stakes and natural context of our experiment, embedded in the actual evaluation of a business plan competition rather than a separate research study with minimal stakes, may help explain the lack of gen-

<sup>&</sup>lt;sup>62</sup>Key pieces of information include profits, employees, assets, liabilities, business age, years in industry, projected revenues, and project employees.

der discrimination that we observe. This highlights the importance of mirroring high-stakes, real-world capital allocation decisions to enhance the external validity of findings.

A third explanation for our differing results is that gender norms and inferences about women's work vary across contexts. Theories of gender discrimination highlight that discrimination is driven by preferences, norms, and inferences, which differ across contexts. Both Brock and De Haas (2023) and Bartŏs et al. (2024) find discrimination concentrated among loan officers with more biased gender attitudes, suggesting preferences play a role. Additionally, the female labor force participation rate is 35.8 percent in Turkiye compared to 57.6 percent in Ethiopia (World Bank, 2024), indicating that discrimination may be more likely in areas with differing norms around women's work.

Overall, this literature suggests that we should expect discrimination in business finance in environments with information scarcity, lower stakes, and/or gender norms that specifically discourage women's participation in business or the labor market. A policy implication is that gender discrimination is likely more significant in accessing start-up capital than for established businesses.

## 5 Conclusion

This paper investigates gender discrimination in capital allocation through a large-scale field experiment in an Ethiopian business plan competition. We obtain clean identification of gender discrimination by randomizing the gender of applicants in the evaluation of the competition. We then evaluate the potential trade-off between gender equity and targeting capital to the highest-performing businesses. We find no evidence of gender discrimination by capital providers. Among 84 loan officers from 13 financial institutions, the gender of the business owner did not influence capital allocation decisions, whether in the competition or loan considerations. These results are consistent across various characteristics of business owners, businesses, and loan officers.

We find that the absence of gender discrimination did not hinder targeting the highest-

performing businesses. Using data we collected from applicants 18 months post-competition and several machine learning algorithms, we find that gender is not a significant predictor of future business performance. This indicates no meaningful trade-off between gender equity and targeting successful businesses. Additionally, it suggests that loan officers' beliefs were accurate enough to make decisions aligned with profit maximization, showing no belief-based (statistical) or preference-based (taste-based) discrimination. Our findings support the theory that discrimination does not persist where it is not profit-maximizing.

Our results caution against assuming that gender discrimination patterns align with gender disparities. In Ethiopia, as in many low-income countries, gender gaps in access to finance persist, contributing to high gender inequality (Klapper and Parker, 2011). It is often assumed that unequal gender norms lead to discrimination and capital misallocation between equally productive men and women. However, our findings show this is not necessarily the case. Indeed, empirical evidence indicates that in developing countries with high gender inequality, discrimination can sometimes favor women of high ability (Delavande and Zafar, 2019; Ayalew, Manian and Sheth, 2021).

Our results suggest that gender discrimination in access to capital is not a major factor in gender gaps in business performance and growth, emphasizing the need for further research on other contributing factors. One key aspect is gender differences in capital demand. The decision to apply for capital may drive the gender gap and explain the lack of discrimination among applicants. In our sample, the gender gap in business performance appears to be smaller than expected in the broader population, suggesting that applying for capital may itself signal business success for women. Additionally, if the decision to apply for a loan is a household decision, it may reflect household support for female-owned businesses (Bernhardt et al., 2019). Thus, applying for capital could signal both business success and household backing and responsibility for the loan. Therefore, we see exploring gender differences for the demand for capital as a promising avenue for future research.
